<b>Abstract:</b>	Novel manganese coordination polymers $\{Mn(fum)(5dmb)(H_2O)_2\}_n$ (1) and $\{[Mn_2(fum)_2(4dmb)_2] \cdot H_2O\}_n$ (2); (fum = fumarato; 5dmb = 5,5'-dimethyl-2,2'-bipyridine; 4dmb = 4,4'-dimethyl-2,2'-bipyridine) were obtained by self-assembly, one-pot, solution reactions at ambient conditions. Fum ligand acquires different coordination modes under different dmb ancillary ligand, which promotes different crystal structure formation, including divergent dimensionality. X-ray single crystal data reveal that 1 crystallizes in a monoclinic system with C2/c space group and forms an infinite one-dimensional (1D) polymer. Mn(II) ion is six-coordinated and displays a distorted octahedral configuration. In addition, the solid-state self-assembly of the polymeric structure of 1 give rise to a 2D supramolecular framework, mainly throughout hydrogen bonding. Whereas, 2 crystallizes in a monoclinic system with a Cc space group and forms an infinite two-dimensional (2D) coordination polymer having dinuclear units. Mn(II) ion displays a distorted octahedral configuration. Thermal stability of the polymers was also determined. Accordingly to variable-temperature magnetic measurements, 1 is paramagnetic and 2 exhibits weak antiferromagnetic coupling between adjacent Mn(II) ions.

## 52 **Introduction**

53  
54

55 Research on the fundamentals of novel coordination polymers continues being relevant due  
56  
57 to the synergic relationship between structural and physicochemical characteristics with  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3  
4 properties; in particular, the search of tailor-made methodologies to suit desired properties  
5  
6 and further applications of these materials, has long been pursued [1]. Several strategies have  
7  
8 been developed to synthesize bivalent-transition metal mixed ligands coordination polymers  
9  
10 containing nitrogen and oxygen donor ligands [2]. Self-assembly of small molecules,  
11  
12 compounds or complexes, has demonstrated to be an appreciated process for synthesizing  
13  
14 large structures with a minimum effort. However, the self-assembly process is sometimes  
15  
16 accompanied by an uncertainty halo, due to unpredictable interactions among metal centers  
17  
18 and ligands, especially when weak forces (i.e. hydrogen bonding,  $\pi$ - $\pi$  interactions) and/or  
19  
20 solvents, such as water, are involved [3]. Moreover, crystal engineering refers to the  
21  
22 construction of crystal structures from organic and metal-organic compounds using design  
23  
24 principles that come from an understanding of the intermolecular interactions in the  
25  
26 molecular solids [4]. Also, supramolecular frameworks based on metal ions and organic  
27  
28 ligands have gained interest recently due to their fascinating structural diversity and their  
29  
30 potential applications in catalysis, sensors, porosity and non-linear optics [5]. Among the  
31  
32 most used bridging ligands for transition metal ions are the dicarboxylate ligands [6]. In  
33  
34 particular, fum ligand has been extensively used for the formation of complexes [7] and  
35  
36 coordination polymers [8]. We selected this ion-bridging ligand due to its simple chemical  
37  
38 structure and its dual chemical functionality, which allow generating complexes or polymers,  
39  
40 depending on its coordination modes. The use of 2,2'-bipyridine as ancillary ligand had  
41  
42 become relevant in our previous studies on complexes [9] and coordination polymers [10] of  
43  
44 transition metals. There are previous reports mainly on structural studies of coordination  
45  
46 polymers formed by the reaction of a Mn(II) salt with fum as bridging ligand and 2,2'-  
47  
48 bipyridine [11], and the related 1,10-phenantroline [12], as co-ligands. Magnetism studies  
49  
50 were not reported for those compounds. Thus, we decided to keep using one of the most  
51

3  
4 studied nitrogen donor ligand [13], and just varying the alkyl-substituent on it, in order to  
5  
6 verify the influence of the co-ligand steric hindrance on the dimensionality and crystalline  
7  
8 structure of coordination polymers. So far, very few articles have been published about the  
9  
10 use of different di-alkyl-2,2'-bipyridines as ancillary ligands, either in transition metal  
11  
12 complexes [14] or coordination polymers [15, 16], and none of them concerning their steric  
13  
14 hindrance influencing structural characteristics and therefore properties.  
15  
16  
17

18  
19 Herein, we describe the easy synthesis, crystalline molecular and supramolecular structures  
20  
21 details, thermal analyses and magnetic properties of novel coordination polymers of Mn(II),  
22  
23 **1** and **2**, bearing fum as bridging ligand and two different dimethyl-2,2'-bipyridine as  
24  
25 ancillary ligands.

## 33 **Experimental**

34  
35  
36  
37

38 All chemicals were of analytical grade, purchased commercially (Aldrich) and were used  
39  
40 without further purification. All syntheses were carried out in aerobic and ambient  
41  
42 conditions. Elemental analyses for C, H, N were carried out for standard methods using a  
43  
44 Vario Micro-Cube analyzer. IR spectra of the complexes were determined as KBr disks in an  
45  
46 Avatar 360 FT-IR Nicolet spectrophotometer from 4000-400  $\text{cm}^{-1}$ . Thermogravimetric  
47  
48 analyses were performed in a TA Instruments equipment, under  $\text{N}_2$  atmosphere, at a heating  
49  
50 rate of 10  $^\circ\text{C min}^{-1}$ , from 20 to 800  $^\circ\text{C}$ . Magnetic characteristics of **1** and **2** were determined  
51  
52 in a MPMS Quantum Design magnetometer with measurements performed at zero field  
53  
54 cooling (ZFC) and field cooling (FC) from 2-300 K and decreasing. The applied magnetic

### 10 11 **Synthesis of $\{\text{Mn}(\text{fum})(5\text{dmb})(\text{H}_2\text{O})_2\}_n$ (1)**

12  
13 A methanol solution (60 ml) of 5,5'-dimethyl-2,2'-bipyridine (0.0921 g; 0.5 mmol) was  
14  
15 added to an aqueous solution (30 ml) of sodium fumarate (0.0800 g; 0.5 mmol) while stirring.  
16  
17 To this solution,  $\text{MnCl}_2 \cdot 4\text{H}_2\text{O}$  (0.0989 g; 0.5 mmol) in 30 ml of de-ionized water was added.  
18  
19 A translucent yellow colored solution was obtained. After four days, small yellow crystals  
20  
21 were obtained then filtered and washed with a 50:50 deionized water-methanol mixture and  
22  
23 air-dried. Yield: 76 % based on metal precursor. Anal. calc. for  $\text{C}_{16}\text{H}_{18}\text{MnN}_2\text{O}_6$   
24  
25 (FW=389.16): C, 49.35; H, 4.62; N, 7.19 %. Found: C, 48.91; H, 4.60; N, 7.09 %. IR ( $\text{cm}^{-1}$ ):

### 39 **Synthesis of $\{[\text{Mn}_2(\text{fum})_2(4\text{dmb})_2] \cdot \text{H}_2\text{O}\}_n$ (2)**

40  
41 A methanol solution (5 ml) of fumaric acid (0.0348 g; 0.3 mmol) was added to an aqueous  
42  
43 solution (5 ml) of sodium hydroxide (0.0240 g; 0.6 mmol), while stirring. Then,  $\text{MnCl}_2 \cdot 4\text{H}_2\text{O}$   
44  
45 (0.0593 g; 0.3 mmol) dissolved in 5 ml of deionized water was added to the previous solution,  
46  
47 under constant stirring. Finally, a methanol solution (5 ml) of 4,4'-dimethyl-2,2'-bipyridine  
48  
49 (0.0552 g; 0.3 mmol) was added. A translucent yellow solution was obtained. After six days,  
50  
51 yellow crystals were obtained then filtered, washed with a 50:50 deionized water-methanol  
52  
53 mixture and air-dried. Yield: 42 % based on metal precursor. Anal. calc. for  $\text{C}_{32}\text{H}_{34}\text{Mn}_2\text{N}_4\text{O}_{11}$

Crystallographic data for **1** and **2** were collected on a Bruker SMART APEX DUO three-circle diffractometer equipped with an Apex II CCD detector using MoK $\alpha$  ( $\lambda = 0.71073 \text{ \AA}$ , Incoatec I $\mu$ S microsource) at 100 K [17]. The crystals were coated with hydrocarbon oil, picked up with a nylon loop, and immediately mounted in the cold nitrogen stream (100 K) of the diffractometer. The structures were solved by direct methods (SHELXS-97) and refined by full-matrix least-squares on F<sup>2</sup> [18] using the shelXle GUI [19]. The hydrogen atoms of the C–H bonds were placed in idealized positions whereas the hydrogen atoms from H<sub>2</sub>O moieties were localized from the difference electron density map, and their position was refined with U<sub>iso</sub> tied to the parent atom with distance restraints. The disordered hydrogens were refined using distance restraints (DFIX). The crystallographic data and refinement details for both polymers are summarized in table 1. Selected bond lengths and angles for **1** and **2** are listed in tables 2 and 3, respectively.

## 50 **Results and discussion**

### 51 **Synthesis and structures**

52  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

Using a very simple methodology of self-assembling solution reactions, equivalent amounts of sodium fumarate (fum), MnCl<sub>2</sub>·4H<sub>2</sub>O, 5,5'-dimethyl-2,2'-bipyridine (5dmb) and 4,4'-

1  
2  
3  
4 dimethyl-2,2'-bipyridine (4dmb), respectively, were mixed in water-methanol solutions,  
5  
6 under ambient conditions. Slow evaporation of solvents yielded light yellow crystals of **1** and  
7  
8  
9 **2**. These crystals are insoluble in common solvents and appear to be air and moisture stable.  
10  
11  $\{\text{Mn}(\text{fum})(5\text{dmb})(\text{H}_2\text{O})_2\}_n$  (**1**) crystallizes in a monoclinic system with C2/c space group and  
12  
13 forms an infinite one-dimensional (1-D) coordination polymer (Fig. 1). The repeat molecular  
14  
15 unit of **1** contains one Mn ion, one fum ligand, one 5dmb co-ligand and two coordinated  
16  
17 water molecules. The coordination environment of the Mn ion is shown in Fig. 1a. The Mn  
18  
19 ion is six-coordinated and surrounded by four oxygen atoms from two different fum ligands  
20  
21 and the two water molecules, and two nitrogen atoms from one 5dmb ligand. The Mn ion  
22  
23 displays a distorted octahedral configuration. The Mn-O bond lengths range from 2.161(5)  
24  
25 to 2.1665(9) Å, while the Mn-N distance is 2.2818(10) Å, which are comparable values to  
26  
27 those found on similar Mn(II) compounds [20, 21, 22]. In **1**, the 1D zig-zag chain is formed  
28  
29 due to the monodentate  $\eta^1:\eta^0$  coordination mode of fum, and the *trans* configuration of its  
30  
31 carboxylate groups, bridging thus the Mn ions (Fig. 1b). It is worthwhile to mention that the  
32  
33 Mn...Mn distance in the 1D chain is 9.885 Å.  
34  
35  
36  
37  
38  
39  
40

41 Intermolecular hydrogen-bonding interactions lead to the formation of a 2D supramolecular  
42  
43 array in **1** (Fig. 2). These interactions are promoted by the presence of the aqua ligand and  
44  
45 the non-coordinated oxygen atom of the fum carboxylate. This can be clearly observed in  
46  
47 Fig. 2a, where the main O-H...O bindings are formed by the O-H moiety (O3) of the aqua  
48  
49 ligand with each of the oxygen atom (O2) of the non-coordinated side of one fum ligand.  
50  
51 This is an intramolecular hydrogen bond. Furthermore, each coordinated water molecule  
52  
53 generates a double hydrogen bridge, the one that is already described above, and another with  
54  
55 one fum oxygen atom (O3) already coordinated to Mn(II) of a neighboring 1D polymeric  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3  
4 chain (intermolecular hydrogen bonding) generating, thus, an extended 2D supramolecular  
5  
6 array (Fig. 2). In this array, the intermolecular Mn...Mn shortest distance is 7.012 Å. In  
7  
8 addition, in the crystalline lattice of **1** there are interchain  $\pi$ - $\pi$  stacking interactions from the  
9  
10 pyridine rings of the 5dmb ligand, with distances of 3.999 and 4.860 Å.  
11  
12  
13

14  
15  $\{[\text{Mn}_2(\text{fum})_2(4\text{dmb})_2]\cdot\text{H}_2\text{O}\}_n$  (**2**) crystallizes in a monoclinic system with a Cc space group  
16  
17 and forms an infinite two-dimensional (2D) coordination polymer. The molecular structure  
18  
19 of **2** consists of two crystallographic independent Mn<sup>2+</sup> ions, two fum ligands, two 4dmb  
20  
21 ligands and one guest H<sub>2</sub>O molecule (Fig. 3). Both Mn ions are six-coordinated and  
22  
23 surrounded by four oxygen atoms from three different fum ligands and two nitrogen atoms  
24  
25 from one 4dmb co-ligand. These Mn ions display a distorted octahedral configuration. The  
26  
27 Mn-O bond lengths vary from 2.084(2) to 2.315(2) Å, whilst the Mn-N distances range from  
28  
29 2.240(3) to 2.265(3) Å, comparable values to those found on related Mn(II) complexes [16,  
30  
31 23, 24, 25]. In compound **1** the fum ligand assumes a  $\mu_4$  coordination mode, in which two  
32  
33 carboxylate groups show the  $\mu_2$ - $\eta^1$ : $\eta^1$  bidentate mode. The carboxylate moieties of fum  
34  
35 alternately bridge adjacent Mn(II) ions in a *syn-syn* configuration generating dinuclear units  
36  
37 in a 1D chain motif. In these units the Mn...Mn shortest separation is 4.561 Å. These  
38  
39 dinuclear units are further linked by another fum ligand in a bridging  $\eta^1$ : $\eta^1$  bidentate fashion,  
40  
41 connecting, thus, the double-ion rows (Fig. 3). These two different coordination modes of  
42  
43 fum ligand to the six-coordinated Mn ions, give rise to a unique 2D wrinkle-sheet array (Fig.  
44  
45 4). Also, in the crystalline lattice of **2** there are interlayer  $\pi$ - $\pi$  stacking interactions from the  
46  
47 pyridine rings of 4dmb ligands, with distances ranging from 3.649 to 5.803 Å.  
48

2  
3  
4 compound. This is, in **1** the 5dmb ancillary ligand may generate a steric hindrance around  
5  
6 the Mn coordination sphere, which precludes the oxygen atoms from the fum ligand to  
7  
8 coordinate further the Mn ions, directing thus to a 1D polymer and, due to the presence of a  
9  
10 coordinated water molecule, into a stable 2D supramolecular structure. While, in **2** the 4dmb  
11  
12 co-ligand possesses a less hindering structure, allowing the fum carboxylates to coordinate  
13  
14 further with Mn before reaching its thermodynamically stable 2D crystal structure.

19  
20

### 21 **Thermogravimetric analyses**

22  
23 To examine the thermal stability of the crystalline polymers, thermal analyses were  
24  
25 performed for **1** and **2** between 20 and 800 °C (Fig. 5).  
26  
27  
28

29  
30 Polymers **1** and **2** exhibit mainly three decomposition stages. The first major weight loss  
31  
32 (10.00 %) for **1** occurs between 120 and 160 °C, the second one, with a weight loss of 46.05  
33  
34 % of the initial weight, takes place approximately between 258 and 325 °C. The last weight  
35  
36 loss (20.34 %) occurs around 390 - 430 °C, from there only 18% of the initial sample weight  
37  
38 remains at 800 °C. Likewise, for **2** the first weight loss (~2.60 %) appears between 97 and  
39  
40 252 °C, the second one, with a weight loss of 48.42%, happens between 275 and 386 °C, and  
41  
42 the third loss (~20 %) occurs from 390 to 445 °C, leaving around 27 % of the initial sample  
43  
44 weight at 800 °C. In both complexes, the first decomposition stage can be endorsed to the  
45  
46 loss of water; however, in **1** two coordinated water molecules are lost, whilst in **2** only one  
47  
48 crystallization water molecule is lost. The rest of the stages can be attributed practically to  
49  
50 the combined weight loss of the fum ligand (calcd. 29.30% for **1** and 31.49% for **2**), and the  
51  
52 5dbpy (calcd. 47.33 %) and the 4dmb (calcd. 50.86 %) co-ligands, respectively. The residual  
53  
54 of the initial weight loss, at 800 °C, for both compounds can be assigned, roughly, to residual  
55  
56  
57

1  
2  
3  
4 MnO (calcd. 18.22 % for **1** and 19.58 % for **2**). It is evident that due to their different  
5  
6 structural characteristics polymer **2** has a superior thermal robustness compared to **1** (Fig. 5).  
7  
8  
9

### 10 11 12 13 **Magnetic properties**

14  
15 DC magnetic susceptibility,  $\chi$ , was determined for **1** and **2**, at zero field cooling (ZFC) and  
16  
17 field cooling (FC) modes, from 2 - 300 K and decreasing, in an applied field of 1000 Oe.  $\chi T$   
18  
19 values at room temperature are 4.14 and 8.85 cm<sup>3</sup>mol<sup>-1</sup>K for **1** and **2**, respectively, which are  
20  
21 close to the values expected for one (4.37 cm<sup>3</sup>mol<sup>-1</sup>K) and two (8.75 cm<sup>3</sup>mol<sup>-1</sup>K)  
22  
23 magnetically isolated Mn<sup>2+</sup> ( $S = 5/2$ ). However, as temperature is lowered,  $\chi T$  value in **1**  
24  
25 remains almost constant (Fig. 6), and only diminishes a bit at very low temperature, which  
26  
27 means that this compound behaves as a paramagnetic system. However, in **2**,  $\chi T$  value  
28  
29 decreases first slowly and then rapidly, as temperature is lowered, until reaching a  $\chi T$  value  
30  
31 of 0.69 cm<sup>3</sup>mol<sup>-1</sup>K at 2 K (Fig. 6). This behavior implies that antiferromagnetic interactions  
32  
33 can be occurring in **2**. For **1**,  $\chi$  and  $\chi^{-1}$  experimental values as a function of  $T$  were fitted to  
34  
35 Curie-Weiss law (Fig. 7), which confirmed that compound **1** only shows a paramagnetic  
36  
37 behavior.  
38  
39

40  
41 Because of the occurrence of dinuclear Mn(II) clusters along the 2D polymer structure in **2**  
42  
43 (Fig. 3b), and due to the  $\chi$  vs.  $T$  plot analysis, where the susceptibility exhibits a maximum  
44  
45 at 5.97 K ( $T_N$ ) after which the  $\chi$  value start to decrease, we believed that this compound would  
46  
47 present antiferromagnetic interactions within the dimeric Mn(II) unit. Therefore, the  
48  
49 experimental data were fit using Bleaney-Bowers equation (1) [26] for a coupled  $S = 5/2$   
50  
51 dimeric unit.  
52  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

$$\chi = (1 - \rho) \frac{N_A g^2 \mu_B^2 (2e^{2J/k_B T})}{k_B (T - \theta) (1 + 3e^{2J/k_B T})} + \rho \frac{N_A g^2 \mu_B^2}{2k_B T} \quad (1)$$

where  $\theta$  is the Curie-Weiss temperature and  $J$  is the magnetic spin exchange interaction according to the Hamiltonian interaction:  $H = -2J (S_1 \cdot S_2)$ , between two Mn magnetic moments in the dimeric unit. The second term in equation (1) refers to the non-interacting paramagnetic species, with the factor  $\rho$  as the molar fraction of these paramagnetic moments,  $k_B$  is the Boltzmann constant,  $N_A$  is the Avogadro number and  $\mu_B$  the Bohr magneton. The best fit of the experimental data was obtained with  $J/k_B = -3.64$  K,  $g = 2.27$ ,  $\theta = -12.8$  K and  $\rho = 6.3\%$  (Fig 8a). Thus, the Bleaney-Bowers equation describes very well the experimental results, confirming the antiferromagnetic interaction between two Mn(II). It is important to mention that this model has been applied for coordination polymers having similar dinuclear units as in compound **2** [27]. Fig. 8b shows the result of the fitting with Curie-Weiss law. The Curie-Weiss plots for **2** gave constants:  $C = 9.26$  cm<sup>3</sup>Kmol<sup>-1</sup>,  $\theta = -15.22$  K, validating, thus, the weak antiferromagnetic exchange occurring between Mn(II) ions in the dinuclear units of **2**. Comparable  $J$  values have been obtained for other similar weak antiferromagnetic systems [28]. So, the magnetic behavior of **2** agrees very well with a weak antiferromagnetic intramolecular interaction between Mn(II) ions, which has been usually found for the *syn-syn*, equatorial-equatorial arrangement in carboxylate bridges of metal ions in analogous dinuclear units [20]. The magnetic behaviors obtained are in very good concordance with the Mn...Mn distances found in **1** and **2**, as a consequence of their structural peculiarities. Polymer **2** exhibits the shortest distance between ions (4.561 Å); therefore, it exhibits magnetic interactions. Whereas, magnetic exchange was not found in **1**, where the metal ions distances fluctuate from 7.012 to 9.885 Å.

## Conclusion

This work reports the easy synthesis and full characterization of two novel Mn coordination polymers formed by fumarato and two different dimethyl-2,2'-bipyridines as co-ligands. In **1**, the bridging ligand coordinates as  $\eta^1:\eta^0$ , yielding a 1D polymer; while in **2**, fum can be found in  $\eta^1:\eta^1$  and  $\mu_2-\eta^1:\eta^1$  modes, generating a 2D structure. It is believed that the origin of these dissimilar structures is the degree of steric hindrance around the coordination sphere of Mn(II) ions, which is provoked by the different position of the methyl groups in the pyridine rings of the dimethyl-2,2'-bipyridines, employed as ancillary ligands. Less hindrance (4dmb) leads to higher structural dimensionality, as in the 2D polymer **2**. The structural differences of compounds **1** and **2** are also reflected in their thermal and magnetic properties. Thus, polymer **1** exhibits only a paramagnetic behavior; whilst, the negative values obtained for  $J$  and  $\theta_{C-W}$  are indicative of intra-dimer Mn(II) weak antiferromagnetic interactions occurring in polymer **2**.

## Supplementary data

CCDC-993491 and 995619 contain supplementary crystallographic data for **1** and **2**, respectively. These data can be obtained free of charge via <http://www.ccdc.cam.ac.uk/conts/retrieving/html>, or from Cambridge Crystallographic Data Center (CCDC), 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (+44) 1223-336-033; Email: [deposit@cdc.cam.ac.uk](mailto:deposit@cdc.cam.ac.uk)].

## Acknowledgments

Authors are indebted to Dr. Diego Martínez-Otero (CCIQS UAEM-UNAM) and M. en C. Alejandra Nuñez (CCIQS UAEM-UNAM) for single-crystal X-ray diffraction and elemental analyses, respectively. Funding for this work was provided by Universidad Autónoma del Estado de México. This work was also supported by CONACyT project 129293, DGAPA-UNAM project IN106014, and ICYTDF, project PICCO. R.E. thanks to A. López, and A. Pompa-Garcia (IIM-UNAM), for help in computational and technical problems.

5 ALERT type 3 Indicator that the structure quality may be low  
0 ALERT type 4 Improvement, methodology, query or suggestion  
1 ALERT type 5 Informative message, check

---

It is advisable to attempt to resolve as many as possible of the alerts in all categories. Often the minor alerts point to easily fixed oversights, errors and omissions in your CIF or refinement strategy, so attention to these fine details can be worthwhile. In order to resolve some of the more serious problems it may be necessary to carry out additional measurements or structure refinements. However, the purpose of your study may justify the reported deviations and the more serious of these should normally be commented upon in the discussion or experimental section of a paper or in the "special\_details" fields of the CIF. checkCIF was carefully designed to identify outliers and unusual parameters, but every test has its limitations and alerts that are not important in a particular case may appear. Conversely, the absence of alerts does not guarantee there are no aspects of the results needing attention. It is up to the individual to critically assess their own results and, if necessary, seek expert advice.

### Publication of your CIF in IUCr journals

A basic structural check has been run on your CIF. These basic checks will be run on all CIFs submitted for publication in IUCr journals (*Acta Crystallographica*, *Journal of Applied Crystallography*, *Journal of Synchrotron Radiation*); however, if you intend to submit to *Acta Crystallographica Section C* or *E*, you should make sure that full publication checks are run on the final version of your CIF prior to submission.

### Publication of your CIF in other journals

Please refer to the *Notes for Authors* of the relevant journal for any special instructions relating to CIF submission.
